
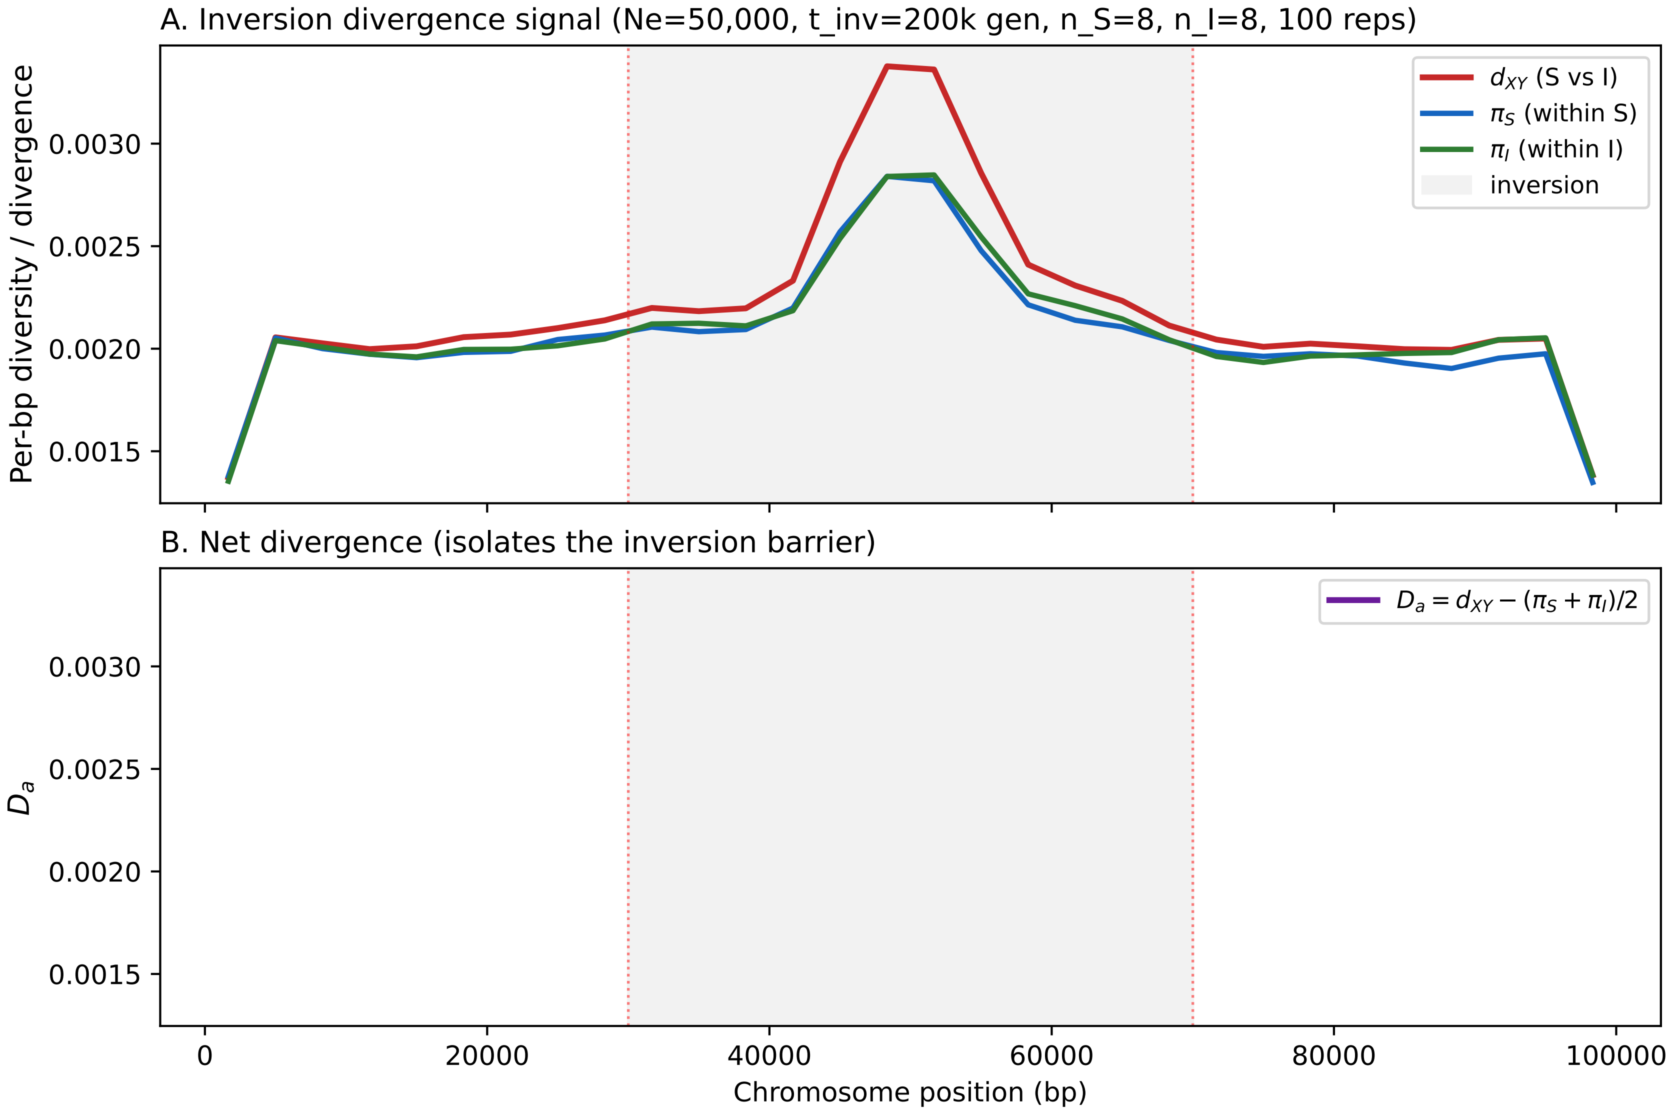

Figure 1. Chromosomal inversion divergence signal simulated with msinv (hull algorithm). (A) Per-bp absolute divergence (d_{XY}) between Standard (S) and Inverted (I) karyotypes is elevated inside the inversion (grey shading, 30–70 kb), while within-class diversity (π_S, π_I) remains at background levels. (B) Net divergence $D_a = d_{XY} - (\pi_S + \pi_I)/2$ isolates the barrier signal; the shared-y-axis shows that D_a is a small fraction of d_{XY} — most apparent divergence is ancestral polymorphism, not fixed differences. Parameters: Ne=50,000, t_inv=200,000 gen, L=100 kb, r=1e-8 bp^{-1} gen^{-1}, μ=1e-8, n_S=8, n_I=8, 100 replicates.
Command: pixi run -e all python examples/make_figures.py
