
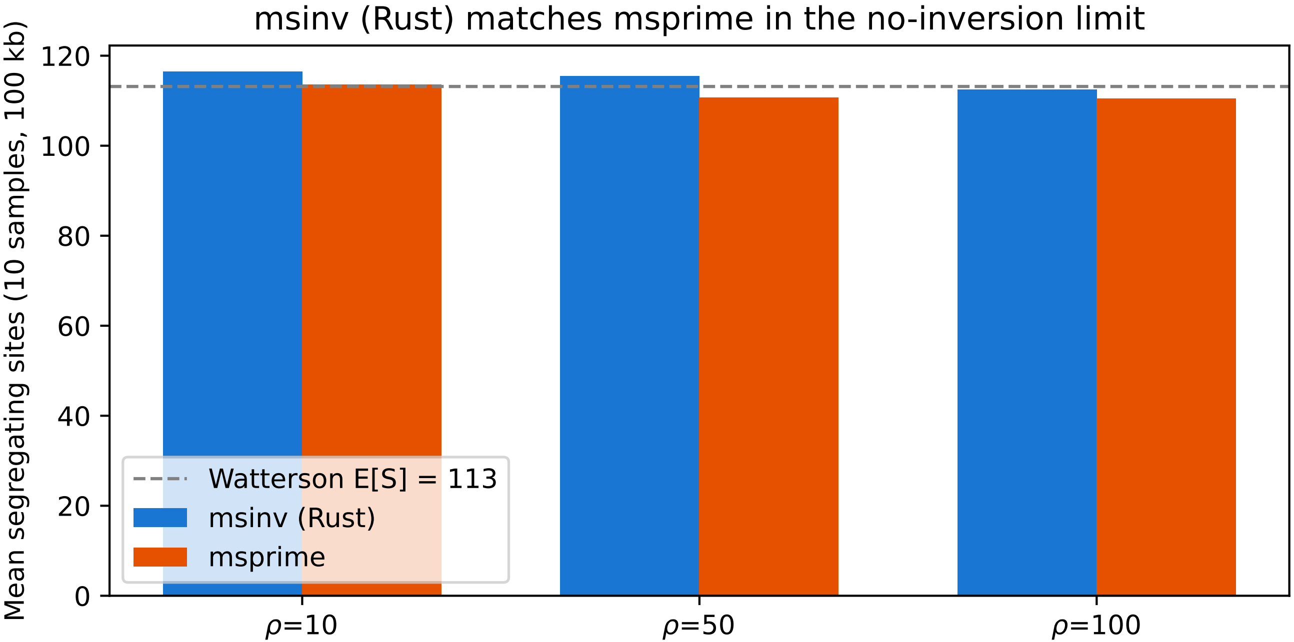

Figure 2. msinv validation against msprime in the no-inversion limit. Mean number of segregating sites from 10 haploid samples across 100 replicates at three recombination rates ($\rho = 4N_e rL$). Without an inversion, msinv produces the same distribution of genealogies as msprime — the two are statistically indistinguishable. Dashed line: Watterson expectation $E[S] = \theta \sum_{i=1}^{n-1} 1/i = 113$. Parameters: Ne=10,000, L=100 kb, μ=1e-8, n=10, 100 replicates per ρ.

Command: pixi run -e all python examples/make_figures.py
