
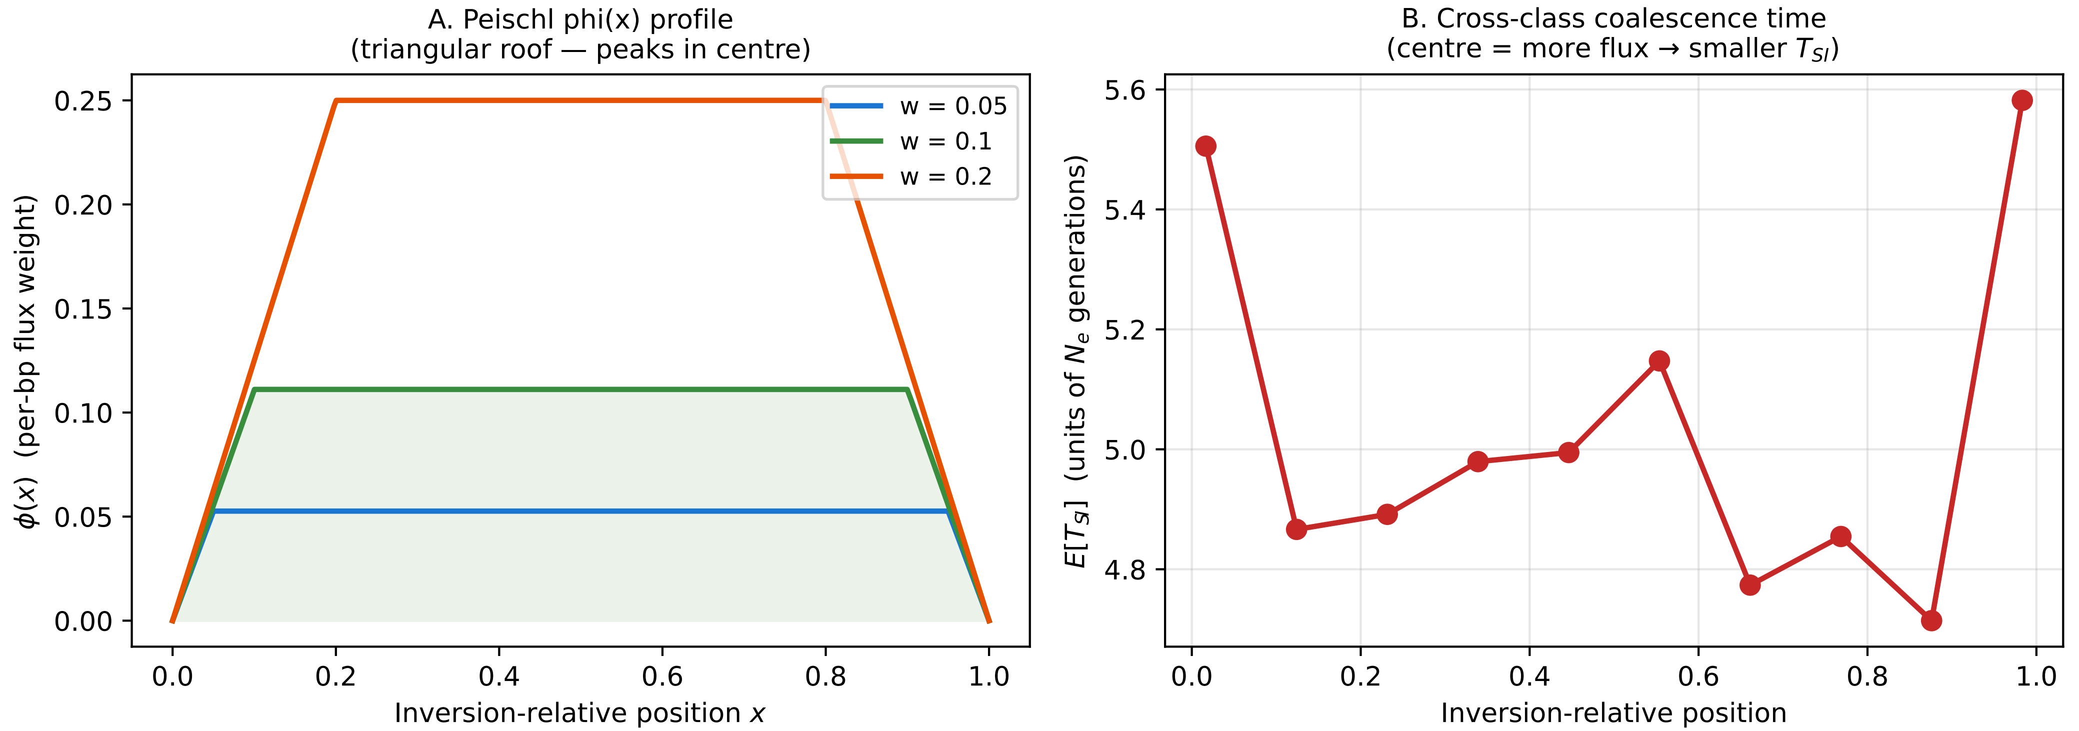

Figure 6. Gene flux profile and its effect on cross-class coalescence time. (A) The Peischl $\phi(x)$ function gives the per-bp gene-conversion weight as a function of position within the inversion — triangular with a peak at the centre and zero at breakpoints. The window parameter w controls the conversion tract length relative to the inversion. (B) Expected cross-class coalescence time $E[T_{SI}]$ as a function of inversion-relative position (Ne=10,000, t_inv=4Ne, γ=1e-7, r=1e-8). T_{SI} is lowest at the centre (where $\phi(x)$ peaks and gene flux is strongest) and highest near breakpoints. 200 replicates per position.
Command: pixi run -e all python examples/make_figures.py
