

Two independent inversions — each gives its own cross-karyotype barrier signal

Figure 4. Two independent inversions on the same chromosome, each generating its own cross-karyotype divergence barrier. Inv A (10–35 kb; $t_{\text{inv}}=100,000$ gen, $p_{\text{inv}}=0.5$, red shading) and Inv B (60–90 kb; $t_{\text{inv}}=300,000$ gen, $p_{\text{inv}}=0.3$, blue shading) show elevated d_{XY} along their respective S-vs-I axes. Inv B is older and produces a stronger signal. The collinear gap between inversions shows background-level divergence on both axes. Sample configuration: 5 SS + 5 II + 4 SI + 4 IS (18 haplotypes, all four karyotype combinations). Parameters: $N_e=30,000$, $L=100$ kb, $\mu=1e-8$, $r=1e-8$, 80 replicates.

Command: `pixi run -e all python examples/make_figures.py`
