

A. Cross-karyotype d_{XY} per inversion axis

B. Hudson F_{ST} per inversion axis

Figure 4. Two independent inversions on the same chromosome. Samples: 5 SS + 5 II + 4 SI + 4 IS (18 haplotypes, all four compound karyotypes). Red axis: S_A (SS+SI) vs I_A (II+IS) — grouped by karyotype at inv A. Blue axis: S_B (SS+IS) vs I_B (II+SI) — grouped by karyotype at inv B. (A) d_{XY} is elevated only inside each inversion along its own axis. (B) Hudson F_{ST} with theory (dashed: $1 - Ne/(t_{inv} + 2Ne)$). Negative F_{ST} clipped to 0. Parameters: $Ne=10000$, $L=100$ kb, $\mu=1e-8$, $r=1e-8$, $\gamma=1e-9$, 80 replicates.
Command: `pixi run -e all python examples/make_figures.py`
